Fractional
approach

Conclusions

References

The Southern women network was collected in 1930s by [Davis et al. \(1941\)](#). It is one of the most analyzed networks in the SNA literature. [Freeman \(2003\)](#) published a meta-analysis in which he reviewed 21 partitions of the set of women obtained by different approaches. In this paper, we present another analysis based on the fractional approach.

The Southern women network is a two-mode network $\mathcal{N} = ((P, E), L)$ describing the social activities of 18 women (first mode, set of persons P) whom they observed over nine-months. During that period, various subsets of these women had met in a series of 14 informal social events (second mode, set of events E) ([UCI, 2008](#)). The participation of women in events determines the set of links L

$$(p, e) \in L \Leftrightarrow \text{woman } p \text{ attended event } e.$$

In the book Davis et al. (1941) two versions of the Southern women network are given. We use the second version (also included in Ucinet). In the first version four links (Dorothy, E10), (Dorothy, E12), (Helen, E13), and (Helen, E14) are missing. Also, in the original data, Myrna is called Myra.

The matrix representation (the ordering of rows/persons and columns/events) provides an early attempt of blockmodeling of two-mode networks.

Fractional
approach

Conclusions

References

In a regular blockmodel each block is either empty or regular – each its row and column is nonempty.

If we join the clusters P_1 and P_2 into a single cluster $P_1 \cup P_2$ we get a regular blockmodel with an empty row (error) for Pearl in the block $(P_1 \cup P_2) \times E_1$. All other blocks are regular or empty without errors.

For the first version of the network, the partition gives a regular blockmodel with an additional empty row (error) for Dorothy in the block $P_3 \times E_3$.

Conclusions

References

The Southern women network contains a (5,4)-core (Cerinšek and Batagelj, 2015) on node subsets $P_{5,4} = \{ \text{Brenda, Laura, Theresa, Evelyn, Nora, Sylvia, Helen, Katherine} \}$ and $E_{5,4} = \{ \text{E3, E5, E6, E7, E8, E9, E10, E12, E13, E14} \}$. Inside the core each woman attended at least 5 events and each event was attended by at least 4 women. Davis identified as the core the same set of women (except Katherine).

The (4,6)-core is induced by the node subsets $P_{4,6} = \{ \text{Brenda, Laura, Eleanor, Theresa, Evelyn, Ruth, Nora, Sylvia, Helen, Myrna, Verne, Dorothy, Katherine} \}$ and $E_{4,6} = \{ \text{E5, E6, E7, E8, E9, E10, E12} \}$.

A traditional (classic) approach (Breiger, 1974; Borgatti and Halgin, 2014) to analysis of a binary two-mode network \mathcal{N} represented with its matrix $\mathbf{PE} = [PE[p, e]]_{P \times E}$ is its transformation to the corresponding one-mode networks:

- *row projection* (projection to the row set P):
 $\mathbf{PP} = \text{row}(\mathbf{PE}) = \mathbf{PE} \cdot \mathbf{PE}^T$
- *column projection* (projection to the column set E):
 $\mathbf{EE} = \text{col}(\mathbf{PE}) = \mathbf{PE}^T \cdot \mathbf{PE}$

These networks are further analyzed using standard methods.

Properties of projections

Fractional
Southern

V. Batagelj

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

The entry $PP[p, q]$ counts the number of ways of moving from person p to person q through some event from E – the number of co-attended events

$$PP[p, q] = |PE(p) \cap PE(q)|$$

where $PE(p) = \{e \in E : PE[e, p] \neq 0\}$ is the set of neighbors in the set E of the node $p \in P$. It holds $\text{outdeg}(p) = |PE(p)|$.

Similarly, $EE[e, f] = |PE(e) \cap PE(f)|$,
 $PE(e) = \{p \in P : PE[e, p] \neq 0\}$ and $\text{indeg}(e) = |PE(e)|$.

For the standard projections it turns out that each node from the other set contributes a complete subgraph on the neighbors in the projection set – nodes with a large degree are over-represented in the projection ([Batagelj, 2020](#)).

Normalized projection

Fractional
Southern
Women

V. Batagelj

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

To make the contribution of each node equal, in bibliometrics proposed the fractional approach (Price and Beaver, 1966) based on the *normalized matrix* $n(\mathbf{PE}) = [n(PE)[p, e]]$ where

$$n(PE)[p, e] = \frac{PE[p, e]}{\max(1, \text{indeg}(e))}$$

The *normalized row projection* \mathbf{PP}_n to the set P is computed as

$$\mathbf{PP}_n = n(\mathbf{PE}) \cdot n(\mathbf{PE})^T$$

The projection matrix is symmetric, $PP_n[p, q] = PP_n[q, p]$. The corresponding network $\mathcal{N}_P = (P, L_P, w_P)$ is undirected with edges (undirected links) $(p : q) = (q : p)$

$$(p : q) \in L_P \Leftrightarrow PP_n[p, q] > 0$$

The weight of the edge $(p : q)$ is set to $w_P((p : q)) = 2PP_n[p, q]$ for $p \neq q$; and $w_P((p : p)) = PP_n[p, p]$. It measures the fractional co-attendance contribution of women p and q .

Newman's normalization

In the case that we would like to have a "fair" projection without loops we can adapt the normalized projection using the *Newman's normalization* (Newman, 2001) $n'(\mathbf{PE}) = [n'(PE)[p, e]]$ where

$$n'(PE)[p, e] = \frac{PE[p, e]}{\max(1, \text{indeg}(e) - 1)}$$

The *loopless normalized row projection* \mathbf{PP}_N to the set P is computed as

$$\mathbf{PP}_N = n(\mathbf{PE}) \cdot n'(\mathbf{PE})^T$$

The projection matrix is symmetric, $PP_N[p, q] = PP_N[q, p]$. The corresponding network $\mathcal{N}'_P = (P, L'_P, w'_P)$ is undirected with edges (undirected links) $(p : q) = (q : p)$

$$(p : q) \in L'_P \Leftrightarrow p \neq q \wedge PP_N[p, q] > 0$$

We remove loops. The weight of the edge $(p : q)$ is set to $w'_P((p : q)) = 2PP_N[p, q]$.

Fractional
approach

Conclusions

References

The picture of the obtained loopless normalized row projection network is not easy readable. To simplify it we determine its *Pathfinder skeleton* for weights $w_{PF} = 1/w_P$ (the PF weight must be a dissimilarity) and $r = \infty$ (see [Schvaneveldt et al. \(1988\)](#) and [Batagelj et al. \(2014\)](#), p. 96–102) preserving the connectivity and the most important edges.

For a given weight d that measures a dissimilarity the Pathfinder algorithm of order $r = \infty$ removes from the undirected network \mathcal{N} all edges $(x : y)$ from triangles on nodes x, y, z with edges satisfying the condition $\max(d(x, z), d(z, y)) < d(x, y)$. The edges of the skeleton on the following slide have the original weights w_P .

```

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

From the skeleton we obtain by cutting the weak edge (Nora : Theresa) a partition in two clusters:

$P_1 = \{\text{Myrna, Dorothy, Verne, Katherine, Sylvia, Nora, Helen, Olivia, Flora}\},$
 $P_2 = \{\text{Theresa, Evelyn, Brenda, Charlotte, Laura, Eleanor, Frances, Pearl, Ruth}\}.$
 Cutting the edges with weight 0.06 would detach only a single node, Pearl.

Partition of events

Fractional
Southern
Women

V. Batagelj

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

Mathematically we could either compute the matrix $n(\mathbf{PE})^T \cdot n(\mathbf{PE})$ or (duality) repeat the same procedure on the matrix $\mathbf{EP} = \mathbf{PE}^T$ and get the normalized row projection to the set of events E .

Unfortunately, it doesn't work well. The problem is the meaningfulness (interpretation) of the corresponding projection. To get a kind of normalized projection to the set of events E we apply the approach proposed in [Batagelj \(2020\)](#).

Let's first compute the matrices $\mathbf{En} = \mathbf{PE}^T \cdot n(\mathbf{PE})$ and $\mathbf{nE} = n(\mathbf{PE})^T \cdot \mathbf{PE}$. The entry

$$En[e, f] = \sum_{p \in PE(e) \cap PE(f)} PE[p, e] \cdot n(PE[p, f])$$

measures the fractional contribution of women to event f co-attended with event e ; and the entry $nE[e, f]$ measures the fractional contribution of women to event e co-attended with event f .

Jaccard column projection

Fractional
Southern
Women

V. Batagelj

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

A *joint co-attendance* contribution can be defined as an average of these two values. Among different options we selected one that gives the *Jaccard column projection* $Jcol(\mathbf{PE})$

$$Jcol[e, f] = \frac{|PE(e) \cap PE(f)|}{|PE(e) \cup PE(f)|}$$

$Jcol$ is symmetric, $Jcol[e, f] = Jcol[f, e]$, and $Jcol[e, e] = 1$.

Considering $|PE(e) \cap PE(f)| = EE[e, f]$ and
 $|PE(e) \cap PE(f)| + |PE(e) \cup PE(f)| = |PE(e)| + |PE(f)| =$
 $\text{indeg}(e) + \text{indeg}(f)$ we get

$$Jcol[e, f] = \frac{EE[e, f]}{\text{indeg}(e) + \text{indeg}(f) - EE[e, f]}$$

The Jaccard column projection $Jcol(\mathbf{PE})$ can be obtained from the ordinary column projection \mathbf{EE} . The corresponding Jaccard network $\mathcal{J} = (E, L_J, Jcol)$ is undirected with loops removed.

Jaccard network

Fractional
Southern

Southern
women
network

Traditional
approach

Fractional
approach

Conclusions

References

Applying the Pathfinder algorithm again to \mathcal{J} ($Jcol$ is a similarity measure, $w_{PF} = 1 - Jcol$) we get a skeleton. Removing the two weakest edges ($E9, E12$) and ($E5, E7$) we get three clusters of events

$$E_1 = \{ E4, E1, E2, E3, E5, E6 \},$$

$$E_2 = \{ E7, E8, E9 \},$$

$$E_3 = \{ E12, E10, E13, E14, E11 \}.$$

Hierarchical clusterings

Fractional

Fractional
approach

Conclusions

References

E₃

P₁

E₂

P₂

E₁

The obtained regular blockmodel is very simple:

- each woman attended at least one event from the cluster E_2 ;
- each woman from the cluster P_2 also attended at least one event from the cluster E_1 , and no event from the cluster E_3 ;
- each woman from the cluster P_1 also attended at least one event from the cluster E_3 , and no event from the cluster E_1 (except Nora).

It is essentially the same as that implied by Davis' second matrix.

We also searched for regular (prespecified) two-mode blockmodels of the Southern women network using the optimization approach (Doreian et al., 2004). In most cases (number of clusters) we obtained several exact (no error) solutions but without an interesting interpretation.

- In the paper, we proposed a new approach to blockmodeling of affiliation / two-mode networks (Persons, Events) based on the fractional approach from bibliometrics. We illustrated it by analyzing the Southern women network. We defined the fractional similarity measure between Persons and the Jaccard similarity measure between Events, both based on fractional co-attendance. To find the clusterings of Persons / Events we can use either the Pathfinder algorithm or the hierarchical clustering. The obtained clusterings determine the blockmodel.
- Freeman's review of the Southern women network analyses deals only with the partitions of the set of women. We considered equally also the partitioning of the set of events and obtained a simple but meaningful regular two-mode blockmodel.
